SHORT REPORT

First detection and molecular characterization of Nebovirus in Brazil

SUMMARY

Nebovirus is a new genus of viruses belonging to the Caliciviridae family recently characterized in cattle, and is associated with gastrointestinal disorders, such as diarrhoea, anorexia and intestinal lesions particularly in calves. The aim of this study was to investigate the prevalence of neboviruses in Brazilian cattle and analyse phylogenetically the virus strains detected. A prevalence of 4·8% of neboviruses in faecal samples from 62 head of cattle from different Brazilian states was detected. All positive animals were aged <20 days and had diarrhoea. Phylogenetic analysis clustered the virus sequences into the Newbury1 clade. There was >96·0% nt (100% aa) sequence identity between the virus sequences in this study and >88·8% nt (>94·4% aa) identity with Newbury1/UK. Our results indicate, for the first time, the occurrence of neboviruses in Brazil as well as in South America, and the first Newbury1-like nebovirus found outside the UK.

Key words: Caliciviridae, cattle diseases, diarrhoea, molecular epidemiology.

Caliciviruses are single-stranded, positive-sense RNA viruses which infect a variety of animal hosts, causing gastrointestinal disorders and even cases of fatal haemorrhage [1, 2]. Of the genera belonging to the family Caliciviridae, the genus Nebovirus was recently characterized in cattle. Neboviruses are on average 7450 nucleotides (nt) long excluding the 3″-poly(A) tail, divided into two open reading frames (ORF); ORF-1 encodes a large non-structural polyprotein contiguous with the major capsid protein and ORF-2 encodes a small basic protein. Gnotobiotic calves experimentally infected with neboviruses showed changes in colour of stools, diarrhoea, anorexia and intestinal lesions [3, 4]. Although there is still no clear definition, the genotypes Nebraska (NB), Newbury1 (NA1) and Dijon have been suggested for this genus [5].

Despite the known relevance of viral agents causing enteric diseases in cattle, there are few studies on the prevalence of viral enteropathogens in Brazil, including predominantly rotavirus [6], coronavirus [7] and astrovirus [8]. We report the first molecular detection and characterization of a nebovirus in South America.
From 15 July 2012 to 25 May 2013, faecal samples were collected from the rectum of 62 cattle (beef and dairy) in rural areas of the states of São Paulo, Minas Gerais, Goiás and Rio Grande do Sul in Brazil. Of the studied animals, 27 (43.5%) had diarrhoea, 39 (62.9%) were aged <4 months, and the majority (51 animals, 82.2%) were female. Fifty-four (87.1%) were raised under the feedlot system and eight (12.9%) under free-range production conditions. Immediately after collection, the samples were kept in plastic bags at -4 °C until processing in the laboratory.

We extracted RNA using TRIzol™ Reagent (Invitrogen, USA). Reverse transcription was performed using ImProm-II™ Reverse Transcription System (Promega, USA) and random primers (Invitrogen), according to the manufacturer’s instructions. Polymerase chain reaction (PCR) targeting the 3′ end of the polymerase gene of neboviruses [9] was done with GoTaq™ Colorless Master Mix (Promega), following manufacturer’s protocol, using the bovine β-actin gene as internal control [10]. The primer sequences used were as follows: NBU-F 5′-TTTCTAACATGGGAYGAYG-3′ and NBU-R 5′-GTCACCTAGTTTTCTCTATA-3′ (549-bp amplicon); actin-F 5′-ACCAGCCATCCAGACAA ACG-3′ and actin-R 5′-ATCTTCAGGGACTTGAC-3′ (360-bp amplicon). The amplified products were gel extracted and sequenced directly on both strands with the same primers used in the PCR, in an automated ABI 3730 DNA Analyser (Applied Biosystems, USA). Nucleotide sequence fragments were edited and assembled into consensus contigs using BioEdit v. 7.0.9 [11]. MEGA 6 [12] was used to perform the multiple sequence alignment and subsequently to build a neighbour-joining phylogenetic tree with bootstrap support. MatGAT v. 2.0[13] was used for sequence identity calculations. Fourteen other nucleotide sequences representative of the three known genotypes for neboviruses were retrieved from GenBank.

Of the samples collected, three (4.8%) were positive for nebovirus by RT-PCR. All positive animals were aged <20 days and had diarrhoea, two positive calves were female, and two positive samples were from beef cattle. Two animals were from the state of Goiás and one from the state of São Paulo.

The samples sequenced in this study shared >96.0% nt (100% aa) sequence identity compared to each other. To reference virus strains of each nebovirus genotype, the viruses in the three samples shared 88.8–89.5% nt (94.4–94.8% aa) identity with Newbury1/UK, 80.0–81.8% nt (87.6–88.4% aa) identity with Nebraska/USA, and 80.8–81.4% nt (86.4–86.5% aa) identity with the respective strains.
identity with DijonA216/FR. Phylogenetic analysis clustered sequences described here into the Newbury1 clade (Fig. 1).

The prevalence in our study was slightly higher than to that reported in Tunisia (3%) [14] and lower than the reported in the France [5] and the United States [9] (7% and 28%, respectively).

In summary, this is the first detection of neboviruses in Brazil as well as in South America, and the first Newbury1-like nebovirus found outside the UK. Nevertheless, a greater number of studies are needed to clarify the epidemiology of the infection by nebovirus in cattle, and evaluation of the prevalence and genetic variation of neboviruses in different countries.

A better understanding of the viruses that cause gastroenteritis in cattle is important for future prevention and control strategies in these animals.

ACKNOWLEDGEMENTS
