Abstract: In this work, the resonance problem in the artificial satellites motion is studied. The development of the geopotential includes the zonal harmonics $J_{20}$ and $J_{40}$ and the tesseral harmonics $J_{22}$ and $J_{42}$. Through successive Mathieu transformations, the order of dynamical system is reduced and the final system is solved by numerical integration. In the simplified dynamical model, two critical angles are studied, $\phi_{2201}$ and $\phi_{4211}$. Numerical results show the time behavior of the semi-major axis and $\phi_2$ angle.

Keywords: Artificial Satellites. Resonance. Orbits.

1 Introduction

Synchronous satellites in circular or elliptical orbits have been extensively used for navigation, communication and military missions. This fact justifies the great attention that has been given in literature to the study of resonant orbits characterizing the dynamics of these satellites since the 60’s (Morando, 1963; Blitzer, 1963; Garfinkel, 1965a; Garfinkel, 1965b; Garfinkel, 1966; Gedeon and Dial, 1967; Gedeon et al., 1967; Gedeon, 1969; Lane, 1988; Jupp, 1969; Ely and Howell, 1996). For example, Molniya series satellites used by the old Soviet Union for communication form a constellation of approximately 110 satellites, launched since 1965, which have highly eccentric orbits with periods of 12 hours. Another example of missions that use eccentric orbits, inclined and synchronous, include satellites to investigate the solar magnetosphere, launched in the 90’s (Neto, 2006).

The orbits of synchronous satellites are very complex. The tesseral harmonics of the geopotential produce multiple resonances which interact resulting significantly nonlinear motions, when compared to non-resonant orbits. It has been found that the orbital elements show relatively large oscillation amplitudes differing from neighboring trajectories, they are in fact chaotic (Ely and Howell, 1996). It should also be noted that the characteristics of several missions involving such orbits require that they are kept to a minimum fuel consumption. Geographic requirements determined by the missions and spatial maneuvers of minimum cost demand precise control of the trajectories that are subjected to significant nonlinearities during the satellite lifetime.

In this paper, the 2:1 resonance is considered; in other words, the satellite completes two revolutions while the Earth carries one.

2 The Resonance Problem

In this section, a simplified Hamiltonian describing the resonant problem is derived through successive Mathieu transformations.

Consider Eq. (1) to the Earth gravitational potential written in classical orbital elements (Osorio, 1973; Kaula, 1966)

$$V = \frac{\mu}{2a} + \sum_{l=2}^{\infty} \sum_{m=0}^{l} \sum_{p=0}^{l} \sum_{q=-\infty}^{\infty} \frac{\mu}{a} \left( \frac{ae}{a} \right)^l J_{lm} F_{lmp} (I) G_{lpq} (e) \cos (\phi_{lmpq} (M, \omega, \Omega, \Theta)), \quad (1)$$

where $\mu$ is the Gaussian constant, $\mu = 3.986009 \times 10^{14}$ m$^3$/s$^2$, $a$, $e$, $I$, $\Omega$, $\omega$, $M$ are the classical keplerian elements.

Presented at the 22nd International Symposium on Space Flight Dynamics, São José dos Campos, Brazil, February, 2011

\(a\) is the semi-major axis, \(e\) is the eccentricity, \(I\) is the inclination of the orbit plane with the equator, \(\Omega\) is the longitude of the ascending node, \(\omega\) is the argument of pericentre and \(M\) is the mean anomaly, respectively; \(a_e\) is the Earth mean equatorial radius, \(a_e = 6378.140\) km, \(J_{lm}\) is the spherical harmonic coefficient of degree \(l\) and order \(m\), \(F_{lmp}(I)\) and \(G_{lmp}(e)\) are Kaula’s inclination and eccentricity functions, respectively. The argument \(\phi_{lmpq}(M, \omega, \Omega, \Theta)\) is defined by

\[
\phi_{lmpq}(M, \omega, \Omega, \Theta) = qM + (l - 2p)\omega + m(\Omega - \Theta - \lambda_{lm}) + (l - m)\frac{\pi}{2},
\]

where \(\Theta\) is the Greenwich sidereal time and \(\lambda_{lm}\) is the corresponding reference longitude along the equator.

In order to describe the problem in Hamiltonian form, Delaunay canonical variables are introduced

\[
L = \sqrt{\mu a} \quad G = \sqrt{\mu a(1 - e^2)} \quad H = \sqrt{\mu a(1 - e^2) \cos(I)}
\]

\(l = M\) \quad \(g = \omega\) \quad \(h = \Omega\). (2)

Using the canonical variables, one gets the Hamiltonian \(\hat{F}\),

\[
\hat{F} = \frac{\mu^2}{2L^2} + \sum_{l=2}^{\infty} \sum_{m=0}^{l} R_{lm} ,
\]

with the disturbing potential \(R_{lm}\) given by

\[
R_{lm} = \sum_{p=0}^{l} \sum_{q=-\infty}^{+\infty} B_{lmpq}(L, G, H)\cos(\phi_{lmpq}(l, g, h, \Theta)) .
\]

The argument \(\phi_{lmpq}\) is defined by

\[
\phi_{lmpq}(l, g, h, \Theta) = ql + (l - 2p)g + m(h - \Theta - \lambda_{lm}) + (l - m)\frac{\pi}{2},
\]

and the coefficient \(B_{lmpq}(L, G, H)\) by

\[
B_{lmpq} = \sum_{l=2}^{\infty} \sum_{m=0}^{l} \sum_{p=0}^{l} \sum_{q=-\infty}^{+\infty} \mu^2 \frac{J_{lm}}{L^2} \left(\frac{\mu a_e}{L^2}\right)^l \int_{\Omega}F_{lmp}(L, G, H)H^q_{l}^{(l+1)}(l-2p)(L, G). \]

The Hamiltonian \(\hat{F}\) depends explicitly on the time through the Greenwich sidereal time \(\Theta\), where \(\Theta = \Omega_e t\) (\(\Omega_e\) is the Earth’s angular velocity and \(t\) is the time). A new variable \(\theta\), conjugated to \(\Theta\), is introduced in order to extend the phase space. In the extended phase space, the extended Hamiltonian \(\hat{H}\) is given by

\[
\hat{H} = \hat{F} + \omega_e \theta .
\]
For resonant orbits, it is convenient to use a new set of canonical variables. Consider the canonical transformation of variables defined by the following relations

\[ X = L, \quad Y = G - L, \quad Z = H - G, \quad \Theta = \Theta \]

\[ x = l + g + h, \quad y = g + h, \quad z = h, \quad \theta = \theta, \quad \text{(8)} \]

where \( X, Y, Z, \Theta, x, y, z, \theta \) are the modified Delaunay variables.

The new Hamiltonian \( \hat{H}' \), resulting from the canonical transformation defined by Eq. (8), is given by

\[ \hat{H}' = \frac{\mu^2}{2X^2} + \omega_c \theta + \sum_{l=2}^{\infty} \sum_{m=0}^{l} R_{lm}', \quad \text{(9)} \]

where the disturbing potential \( R_{lm}' \) is given by

\[ R_{lm}' = \sum_{p=0}^{l} \sum_{q=-\infty}^{+\infty} B_{lmpq}'(X, Y, Z) \cos(\varphi_{lmpq}(x, y, z, \Theta)). \quad \text{(10)} \]

Consider the resonance to be studied in this work; that is, the commensurability between the Earth rotation angular velocity \( \Omega_e \) and the mean motion \( n \). This commensurability can be expressed as

\[ qn - m\omega_e \cong 0 \quad \text{(11)} \]

classifying \( q \) and \( m \) as integers. The commensurability of the resonance studied, \( q/m \), is defined by \( \alpha \). When this commensurability occurs, small divisors, associated to the tesseral harmonics, arise in the integration of the equations of motion (Lane, 1988). These terms are called resonants.

The short and long period terms can be eliminated from the Hamiltonian \( \hat{H}' \) by applying an averaging method. A reduced Hamiltonian \( \hat{H}_r \) is obtained from the Hamiltonian \( \hat{H}' \) when only secular and resonant terms are considered. Several authors, Kaula (1966), Lima Jr (1998), Formiga and Vilhena de Moraes (2009), Vilhena de Moraes et al. (1995), Ely and Howell (1996) also use this simplified Hamiltonian to study the resonance. The reduced Hamiltonian \( \hat{H}_r \) is given by

\[ \hat{H}_r = \frac{\mu^2}{2X^2} + \omega_c \theta + \sum_{j=1}^{\infty} B_{2j,0,0,0}(X, Y, Z) + \sum_{l=2}^{\infty} \sum_{m=2}^{l} \sum_{p=0}^{l} B_{lmpq}'(X, Y, Z) \cos(\varphi_{lmpq}(x, y, z, \Theta)). \quad \text{(12)} \]

The canonical system of differential equations governed by \( \hat{H}_r \) has the first integral

\[ \left( 1 - \frac{1}{\alpha} \right) X + Y + Z = C_1 \quad \text{(13)} \]
where $C_1$ is an integration constant.

Using this first integral, a Mathieu transformation

$$(X, Y, Z, \Theta, x, y, z, \theta) \rightarrow (X_1, Y_1, Z_1, \Theta_1, x_1, y_1, z_1, \theta_1)$$

can be defined.

This transformation is given by the following equations

$$X_1 = X, \quad Y_1 = Y, \quad Z_1 = \left(1 - \frac{1}{\alpha}\right)X + Y + Z, \quad \Theta_1 = \Theta$$

$$x_1 = x - \left(1 - \frac{1}{\alpha}\right)z, \quad y_1 = y - z, \quad z_1 = z, \quad \theta_1 = \theta.$$

The subscript 1 denotes the new set of canonical variables. Note that $Z_1 = C_1$ and the $z_1$ is an ignorable variable. So, the order of the dynamical system is reduced in one degree of freedom.

Substituting the new set of canonical variables, $X_1, Y_1, Z_1, \Theta_1, x_1, y_1, z_1, \theta_1$, in the reduced Hamiltonian given by Eq. (12), one gets the resonant Hamiltonian. The word "resonant" is used to denote the Hamiltonian $\hat{H}_{1,rs}$ which is valid for any resonance. The periodic terms in this Hamiltonian are resonant terms. The Hamiltonian $\hat{H}_{1,rs}$ is given by

$$\hat{H}_{1,rs} = \frac{\mu^2}{2X_1^2} + \omega \theta_1 + \sum_{j=1}^{\infty} B_{1,2j,0j,0}(X_1, Y_1, Z_1) +$$

$$+ \sum_{l=2}^{\infty} \sum_{m=2}^{l} \sum_{p=0}^{l} B_{1,lm,lp}(X_1, Y_1, Z_1)\cos(\phi_{1,lm}(\alpha m)(x_1, y_1, z_1, \Theta_1)).$$

The Hamiltonian $\hat{H}_{1,rs}$ has all resonant frequencies, relative to the commensurability $\alpha$, where the $\phi_{1,lm}(\alpha m)$ argument is given by

$$\phi_{1,lm}(\alpha m) = m(\alpha x_1 - \Theta_1) + (l - 2p - \alpha m)y_1 - \phi_{1,lm}(\alpha m)0,$$

with

$$\phi_{1,lm}(\alpha m)0 = m\lambda_{lm} - (l - m)\frac{\pi}{2}.$$

The secular and resonant terms are given, respectively, by $B_{1,2j,0j,0}(X_1, Y_1, Z_1)$ and $B_{1,lm,lp}(X_1, Y_1, Z_1)$.

Each one of the frequencies contained in $\frac{dx_1}{dt}, \frac{dy_1}{dt}, \frac{d\theta_1}{dt}$ is related, through the coefficients $l, m, p$ and keeping $q/m$ fixed, one finds, all frequencies $\frac{d\phi_{1,lm}(\alpha m)}{dt}$ concerning to a specified resonance.
Now, consider a single frequency among the several resonant frequencies that can be obtained from the expression

\[ \frac{\phi_{1,\text{imp}(am)}}{dt} = m \left( \alpha \frac{dx_1}{dt} - \frac{d\Theta_1}{dt} \right) + (l - 2p - m\alpha) \frac{dy_1}{dt}. \] (18)

The frequency \( \dot{\phi}_{1,\text{imp}(am)} \) for the fixed coefficients \( m \) and \( (l - 2p - m\alpha) \) will be the unique resonant frequency considered in the resonant Hamiltonian \( \dot{H}_{1,rs} \). This frequency will be called “critical frequency”.

A critical frequency can be, for example, the one that results in a smaller numerical value for \( \dot{\phi}_{1,\text{imp}(am)} \), implying a effect strengthening of the resonance considered. The frequencies of the arguments \( \Omega \) and \( \omega \) can become more pronounced the presence of small divisors that arise in the integration of the motion equations, this depend also on the eccentricity and inclination of the orbit plane. The importance of the node and the pericentre frequencies is smaller when compared to the mean anomaly and Greenwich sidereal time, however, they also have their contribution in the resonance effect. As mentioned in preceding paragraphs, the coefficients \( l, m, p \) can vary, producing different frequencies within the resonant cosines for the same resonance. These frequencies are slightly different, with small variations around the commensurability given by \( \alpha \dot{x}_1 \cdot \dot{\Theta}_1 \).

In the keplerian elements, the coefficient of frequency \( \dot{\omega} \) assumes the values 2, 0, -2, and the coefficient of frequency \( \dot{y}_1 \) assumes the values 1, -1, -3.

According to Eq. (16), the argument in the resonant Hamiltonian is given by

\[ \phi_{1,\text{imp}(am)}(x_1, y_1, \Theta_1). \] To determine a critical frequency, one needs to fix all the coefficients of the variable \( x_1 \), \( y_1 \), \( \Theta_1 \); in other words, one fixes \( \alpha \), \( m \) and \( (l-2p-m\alpha) \).

The coefficient \( \alpha \) is fixed, because the type of resonance is defined; in this paper 2:1. Once the resonant angle has been chosen, the coefficients \( m \) and \( (l-2p-m\alpha) \) must be fixed too.

By fixing the expression \( l - 2p \) instead of the coefficients \( l \) and \( p \) separately, one has the possibility to vary \( l \) and \( p \), considering that \( l - 2p \) is a certain fixed value \( k \). Once this critical frequency has been chosen among the possible resonant frequencies, the other periodic terms of the Hamiltonian \( \dot{H}_{1,rs} \) are taken as short period terms, with frequencies different from the critical frequency.

Defining a single critical frequency, or, assuming the isolated study of each frequency, a new Hamiltonian is obtained. This new Hamiltonian is given by

\[ \dot{H}_{1,c} = \mu^2 \frac{2}{X_1^2} + \omega_1 \dot{\theta}_1 + \sum_{j=1}^{\infty} B_{1,2j,0,j,0}(X_1, Y_1, C_1) + \]

\[ + \sum_{l=2}^{\infty} \sum_{p=0}^{l} B_{1,\text{imp}(am)}(X_1, Y_1, C_1) \cos(\phi_{1,\text{imp}(am)}(x_1, y_1, \Theta_1)). \] (19)

The coefficients \( k = l - 2p \) and \( m \) are fixed. This Hamiltonian contains secular and critical terms only. Since \( k \) is a fixed value, \( \dot{H}_{1,c} \) can be put in the simplified form

\[ \dot{H}_{1,c} = \mu^2 \frac{2}{X_1^2} + \omega_1 \dot{\theta}_1 + \sum_{j=1}^{\infty} B_{1,2j,0,j,0}(X_1, Y_1, C_1) + \]

\[ + \sum_{p=8}^{\infty} B_{1,\text{imp}(am)}(X_1, Y_1, C_1) \cos(\phi_{1,\text{imp}(am)}(x_1, y_1, \Theta_1)), \] (20)

where \( \mu^2 \frac{2}{X_1^2} + \omega_1 \dot{\theta}_1 \) is the central part of the Hamiltonian, \( \sum_{j=1}^{\infty} B_{1,2j,0,j,0}(X_1, Y_1, C_1) \) contains only secular terms with the even zonal harmonics, and
\[ \sum_{p=s}^{\infty} B_{1,(2p+k)mp(\alpha m)}(X_1, Y_1, C_1) \cos \phi_1_{1,(2p+k)mp(\alpha m)}(x_1, y_1, \Theta_1) \]

represents the resonant terms that have the same critical frequency.

The canonical system of differential equations governed by the Hamiltonian \( \dot{H}_{1,c} \) has the first integral

\[ (k - m\alpha)X_1 - m\alpha Y_1 = C_2 , \]  \hspace{1cm} (21)

where \( C_2 \) is an integration constant.

Using this integral, a new Mathieu transformation can be defined. This canonical transformation is given by the following equations

\[ X_2 = X_1 \hspace{1cm} Y_2 = (k - m\alpha)X_1 - m\alpha Y_1 \hspace{1cm} \Theta_2 = \Theta_1 \]

\[ x_2 = x_1 + \left( \frac{k - m\alpha}{m\alpha} \right) y_1 \hspace{1cm} y_2 = -\frac{1}{m\alpha} y_1 \hspace{1cm} \theta_2 = \theta_1. \]  \hspace{1cm} (22)

The subscript 2 denotes the new set of canonical variables.

The Hamiltonian function is invariant with respect to this new Mathieu transformation. Thus, from Eq. (20) and (22), one gets the final Hamiltonian \( \dot{H}_{2,f} \)

\[ \dot{H}_{2,f} = \frac{\mu^2}{2X_2^2} + \omega_c \theta_2 + \sum_{j=1}^{\infty} B_{2,2j,0,j,0}(X_2, C_1, C_2) + \]
\[ + \sum_{p=s}^{\infty} B_{2,(2p+k)mp(\alpha m)}(X_2, C_1, C_2) \cos (\phi_{2,(2p+k)mp(\alpha m)}(x_2, \Theta_2)), \]  \hspace{1cm} (23)

where \( \sum_{j=1}^{\infty} B_{2,2j,0,j,0}(X_2, C_1, C_2) \) represents the secular terms and

\[ \sum_{p=s}^{\infty} B_{2,(2p+k)mp(\alpha m)}(X_2, C_1, C_2) \cos \phi_{1,(2p+k)mp(\alpha m)}(x_2, \Theta_2) \]

represents the resonant terms with the same critical frequencies. Note that \( Y_2 = C_2 \) and \( y_2 \) is an ignorable variable.

The new angle \( \phi_{2,(2p+k)mp(\alpha m)}(x_2, \Theta_2) \) is given by

\[ \phi_{2,(2p+k)mp(\alpha m)}(x_2, \Theta_2) = \phi_2 - \phi_{2,(2p+k)mp(\alpha m),0} ; \]  \hspace{1cm} (24)

where \( \phi_2 = m(\alpha x_2 - \Theta_2) \), and
where the function $G^\prime$ is the Kaula’s eccentricity function. Prime denotes the simplified Hamiltonian for small eccentricities.

Accordingly, the Hamiltonian $\hat{H}',\beta$ can be rewritten as

$$\hat{H}',\beta = \frac{\mu^2}{2X^2} + \omega_e \theta_2 + \sum_{j=1}^{\infty} B_{2,2j,0,0}(X_2, C_1, C_2) +$$

$$+ \sum_{p=S}^{\infty} B_{2,(2p+k)mp(\alpha m)}(X_2, C_1, C_2) \cos(\phi_{2,(2p+k)mp(\alpha m)}(x_2, \Theta_2)),$$

with

$$B_{2,(2p+k)mp(\alpha m)}(X_2, C_1, C_2) = \frac{\mu^{2p+k+2}}{X^{4p+2k+2}} a_{2p+k}^2 j_{(2p+k)m} \times$$

$$\times F_{(2p+k)mp}(X_2, C_1, C_2) G_{(2p+k)mp(\alpha m)}(X_2, C_2),$$

where the function $G_{lpp}(\epsilon)$ is the Kaula’s eccentricity function. Prime denotes the simplified Hamiltonian for small eccentricities.

The dynamical system generated by Hamiltonian $\hat{H}',\beta$ is

$$\frac{dX_2}{dt} = -m\alpha \sum_{p=S}^{\infty} B_{2,(2p+k)mp(\alpha m)}(X_2, C_1, C_2) \cos(\phi_{2,(2p+k)mp(\alpha m)}(x_2, \Theta_2)).$$

(29)

$$\frac{d\phi_2}{dt} = m\alpha \frac{\mu^2}{X^2} - m\omega_e - m\alpha \sum_{j=1}^{\infty} \frac{\partial B_{2,2j,0,0}(X_2, C_1, C_2)}{\partial X_2} -$$

$$- m\alpha \sum_{p=S}^{\infty} \frac{\partial B_{2,(2p+k)mp(\alpha m)}(X_2, C_1, C_2)}{\partial X_2} \cos(\phi_{2,(2p+k)mp(\alpha m)}(x_2, \Theta_2)).$$

(30)

The Eq. (29) and (30) represent the motion equations in a resonance of commensurability $\alpha$.

3 Results

Figures (1) to (8) show the time behavior of the semi-major axis and $\phi_2$ angle, according to the numerical integration of the motion equations, (29) and (30). The initial conditions, in the Figs. (1) to (8), for inclinations are $10^\circ$ and $55^\circ$, and eccentricities, 0.001 and 0.01. The initial values of semi-major axis are around the critical semi-major axis. Note that the circulation and libration regions are differentiated by color.
Figure 1. $\phi_2$ versus $t$, considering the tesseral harmonic $J_{22}$. The initial conditions for inclination and eccentricity are $I = 10^\circ$ and $e=0.001$, respectively.

Figure 2. $a$ versus $t$, considering the tesseral harmonic $J_{22}$. The initial conditions for inclination and eccentricity are $I = 10^\circ$ and $e=0.001$, respectively.
Figure 3. $\phi_2$ versus t, considering the tesseral harmonic $J_{22}$. The initial conditions for inclination and eccentricity are $I = 55^\circ$ and $e=0.001$, respectively.

Figure 4. $a$ versus t, considering the tesseral harmonic $J_{22}$. The initial conditions for inclination and eccentricity are $I = 55^\circ$ and $e=0.001$, respectively.
Figure 5. $\phi_2$ versus $t$, considering the tesseral harmonic $J_{22}$. The initial conditions for inclination and eccentricity are $I = 10^\circ$ and $e=0.01$, respectively.

Figure 6. $a$ versus $t$, considering the tesseral harmonic $J_{22}$. The initial conditions for inclination and eccentricity are $I = 10^\circ$ and $e=0.01$, respectively.
Figure 7. $\phi_2$ versus $t$, considering the tesseral harmonic $J_{22}$. The initial conditions for inclination and eccentricity are $I = 55^\circ$ and $e=0.01$, respectively.

Figure 8. $a$ versus $t$, considering the tesseral harmonic $J_{22}$. The initial conditions for inclination and eccentricity are $I = 55^\circ$ and $e=0.01$, respectively.
Figures (1) to (8) show that vibration amplitudes increasing when the inclination varies from $10^\circ$ to $55^\circ$ and when the eccentricity varies from 0.001 to 0.01. Figures (9) and (10) show the time behavior of the semi-major axis and $\phi_2$ angle, considering the critical angle $\phi_{2201}$ associated to tesseral harmonic $J_{22}$ and the critical angle $\phi_{4211}$ associated to tesseral harmonic $J_{42}$. The Table 1 show the resonant coefficients.

### 4 Conclusions

In this work, the dynamical behavior of two critical angles associated to the 2:1 resonance problem in the artificial satellites motion have been investigated. Through successive canonical transformations, a simplified model describing the problem is derived. In the regular motion region, one can study the dynamical system considering each critical angle separately.

The results show the time behavior of the semi-major axis and $\phi_2$ angle, considering two inclinations, $10^\circ$ and $55^\circ$, and different eccentricities, 0.001 and 0.01. Two different regions are observed in the numerical integration, libration and circulation regions.

Two critical angles are studied, $\phi_{2201}$ associated to $J_{22}$ and $\phi_{4211}$ associated to $J_{42}$. The values of the critical semi-major axis show a difference of centimeters in the libration region, when the tesseral harmonic $J_{42}$ is added.

Inside the region where the resonances are found, the motion can be chaotic, because it shows sensibility to initial conditions.
